

**CALIFORNIA STATE SCIENCE FAIR  
2017 PROJECT SUMMARY**

<b>Name(s)</b> <b>Blake T. Scurry</b>	<b>Project Number</b> <b>J0120</b>
<b>Project Title</b> <b>The Need for Speed: Optimum Angle of Attacks for a Race Car Rear Airfoil</b>	
<p style="text-align: center;"><b>Abstract</b></p> <p><b>Objectives/Goals</b> The objective of this project is to determine what kind of airfoil or spoiler based on angle of attack provides the best turning performance with the best speed.</p> <p><b>Methods/Materials</b> This experiment was conducted by creating a low speed wind tunnel built of cardboard, wood, Plexiglas, and used a house fan for wind generation. It was built to test the effects of changing angle of attack on a symmetrical airfoil. Dry ice was used for flow visualization. The airfoil is made of foam and cut using a hot wire cutter. The data was collected through photography at various fan speeds and angles of attack of the airfoil.</p> <p><b>Results</b> The results of the images of the airflow over the airfoil or wing and the angle of attack where the flow started to separate correlated to the hypothesis of what was predicted for optimum down force.</p> <p><b>Conclusions/Discussion</b> Despite limitations to the experiment using a home built wind tunnel, The hypothesis was validated through use of photography and analysis. The optimum airfoil for a race car needs to be designed with a -20 degree angle of attack to produce the best traction and braking performance.</p>	
<b>Summary Statement</b> Flow visualization proved optimum down force occurred at -20 degrees angle of attack to due to initial flow separation	
<b>Help Received</b> My father helped me construct the wind tunnel I designed based on research. My father, teacher and neighbor who is an engineer reviewed my work.
